Received 20 January 2021, revised and accepted 07 April 2021

#### Abstract

An attempted incorporation of N -donor ligand in the coordination sphere of Ca in the molecular solid $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(4-\mathrm{nba})_{2}\right]$ (4-nba=4-nitrobenzoate) resulted in the formation of the one-dimensional (1D) coordination polymers catena-[bis ( $\mu-4$ -nitrobenzoato)-diaqua-calcium 4,4'-bipyridine] 1 and catena-[bis( $\mu$-4-nitrobenzoato)-diaqua-calcium 1H-1,2,4-triazole] 2 with the N -heterocycle functioning as a solvate. The syntheses, crystal structures and properties of $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(4-\mathrm{nba})_{2}\right] \cdot \mathrm{L}$ ( $\mathrm{L}=4,4^{\prime}$-bipyridine $\mathbf{1} ; \mathrm{L}=1 \mathrm{H}-1,2,4$-triazole $\mathbf{2}$ ) are reported. The central $\mathrm{Ca}(\mathrm{II})$ in $\mathbf{1}$ and $\mathbf{2}$ exhibits eight-coordination and the aqua ligands are terminal, while 4-nitrobenzoate functions as a $\mu_{2}$-bridging ligand. The $\mu_{2}-\eta^{2}: \eta^{1}$ tridentate binding mode of the 4 -nba ligand results in the formation of an infinite chain of edge-sharing $\left\{\mathrm{CaO}_{8}\right\}$ polyhedra flanked by the 4-nitrobenzoates. The solvate 4,4 '-bipyridine in $\mathbf{1}$ (or 1,2,4-triazole in $\mathbf{2}$ ) links adjacent polymeric chains with the aid of $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonding interactions. A comparative study of $\left\{\mathrm{CaO}_{\mathrm{x}}\right\}$ polyhedral linking in structurally characterized calcium coordination polymers based on 4-nitrobenzoate is described.

Keywords: Calcium, 4-Nitrobenzoate, 1,2,4-triazole; 4,4'-Bipyridine, Coordination polymer, Edge-sharing $\left\{\mathrm{CaO}_{8}\right\}$ polyhedra

A recent review article titled "Calcium-based MetalOrganic Frameworks and their potential applications" provides an overview of the recent developments in the area of metal-organic frameworks (MOFs) of $\mathrm{Ca}^{1}$. A total of one hundred and eighty four structurally characterized compounds of Ca of varying dimensionalities ranging from molecular solids (zero-dimensional) to three-dimensional framework materials are described in the review discussing synthetic methodologies, crystal structures, important properties and related applications. Although most syntheses are performed under solvotherml conditions ${ }^{2-13}$, other methodologies like microwave syntheses ${ }^{14}$, mechanochemical synthesis ${ }^{15}$, ultrasonic irradiation ${ }^{16}$ etc. have also been employed for preparation of compounds.

Several papers have appeared in the literature ${ }^{17-33}$ which describe the acid base reactions of calcium sources with a carboxylic acid under non-hydrothermal conditions and structural characterization of the product. In many of these compounds the solvent water molecules tend to occupy one or more of the coordination sites of Ca (II) due to the high hydration energy of the Ca centres. In some cases for example L-tartaric acid ${ }^{17}$, the reaction can result in a three-
dimensional product while in some cases for example 4-nitrobenzoic acid (4-nbaH), a molecular solid $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(4-\mathrm{nba})_{2}\right] 3^{25}$ is the product of the reaction. In the monomeric compound 3 all the four aqua ligands are terminal, and the unique 4 -nba ligands exhibit monodentate ( $\eta^{1}$ ) and bidentate ( $\eta^{2}$ ) binding ${ }^{1}$. With 4 -nbaH, a water-rich dinuclear compound viz. $\operatorname{bis}\left(\mu_{2}-\right.$ aqua)-octa-aqua-bis(4-nitrobenzoato)-di-calcium(II) bis(4-nitrobenzoate) octahydrate having formula $\left[\left(\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(4-\mathrm{nba}) \mathrm{Ca}\right)_{2}\left(\mu_{2}-\mathrm{H}_{2} \mathrm{O}\right)_{2}\right](4-\mathrm{nba})_{2} \cdot 8 \mathrm{H}_{2} \mathrm{O}$ has also been structurally characterized ${ }^{30}$. The role of temperature for product formation was also highlighted in the review on $\mathrm{Ca}-\mathrm{MOFs}^{1}$. High temperature generally favours higher dimensionality and reactions at low temperature or room temperature result in lowdimensional structures.

In earlier work from our laboratory, we have demonstrated that the monomeric tetra(aqua) $\mathrm{Ca}(\mathrm{II})$ compound 3 can be transformed into the onedimensional coordination polymers $\left[\mathrm{Ca}\left(\mathrm{L}^{1}\right)(4-n b a)_{2}\right]$ $\left(\mathrm{L}^{1}=\mathrm{N} \text {-methylimidazole }\right)^{34}$ or $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{L}^{2}\right)(4-\mathrm{nba})_{2}\right]$ ( $\mathrm{L}^{2}=2$-methylimidazole) $)^{35}$ by the incorporation of N donor ligands $\mathrm{L}^{1}$ or $\mathrm{L}^{2}$ accompanied by the complete or partial removal of the aqua ligands. Our attempts to incorporate a bridging N -donor ligand like 4,4'-
bipyridine (or 1,2,4-triazole) resulted in the formation of the new calcium(II) coordination polymers catena-[bis( $\mu$-4-nitrobenzoato)-diaqua-calcium 4,4'bipyridine] 1 and catena-[bis( $\mu$-4-nitrobenzoato)-diaqua-calcium $1 \mathrm{H}-1,2,4$-triazole] having formula $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(4-\mathrm{nba})_{2}\right] \cdot \mathrm{L}\left(\mathrm{L}=4,4^{\prime}\right.$-bipyridine $\mathbf{1}$; $\mathrm{L}=1,2,4-$ triazole 2) with the N -hetreocycle functioning as a solvate and linking adjacent polymeric chains with the aid of $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$ hydrogen bonding interactions. The results of these investigations are described herein.

## Materials and Methods

All the chemicals used in this study were of reagent grade and used as received. The starting materials and reaction products are air stable and hence were prepared under normal laboratory conditions. The molecular solid $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(4-\mathrm{nba})_{2}\right] \mathbf{3}$ was prepared as per a reported procedure ${ }^{25}$. Infrared (IR) spectra of the solid samples diluted with KBr were recorded on a Shimadzu (IR Prestige-21) FT-IR spectrometer in the range $4000-400 \mathrm{~cm}^{-1}$. UV-visible absorption spectra of aqueous solutions of $\mathbf{1}$ and $\mathbf{2}$ were recorded on a Shimadzu UV-2450 double beam spectrophotometer using matched quartz cells. Luminescence spectra of the solid samples were recorded at room temperature using Perkin Elmer LS 55 spectrophotometer. Raman spectra were recorded using 785 nm radiation for excitation on an Agiltron Peak Seeker Pro Raman instrument from 4000 to $200 \mathrm{~cm}^{-1}$. Thermal studies were performed in flowing air, in $\mathrm{Al}_{2} \mathrm{O}_{3}$ crucibles on a STA-409PC simultaneous thermal analyzer from Netzsch. A heating rate of $10 \mathrm{~K} \mathrm{~min}^{-1}$ was employed for all measurements. Isothermal mass loss studies were performed in a temperature-controlled electric furnace. Microwave reactions were performed in a domestic microwave oven. Elemental analyses (C, H and N) were performed on a Variomicro cube CHNS analyser.

Synthesis of $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(4-\mathrm{nba})_{2}\right] \cdot \mathrm{L} \quad$ (4-nba=4-nitrobenzoate; $\mathbf{L}=4,4$ '-bipyridine $1 ; \mathbf{L}=1,2,4$-triazole 2)

Compound 3 ( $0.889 \mathrm{~g}, 2 \mathrm{mmol}$ ) was dissolved in distilled water ( $\sim 40 \mathrm{~mL}$ ) by microwaving it for 1 min on medium power setting. Then $4,4^{\prime}$-bipyridine ( $0.312 \mathrm{~g}, 2 \mathrm{mmol}$ ) was added and the reaction mixture was microwaved for 2 min . The hot clear reaction mixture was left aside for crystallization. Fine transparent crystals of $\mathbf{1}$ suitable for structure determination which separated after $\sim 1-3 \mathrm{~h}$ were isolated by decanting the filtrate, washed with a little ice cold water followed by ether and air dried
(yield: $73 \%$ ). Alternatively, $\mathbf{1}$ can be prepared by dissolution of a mixture of $3(0.889 \mathrm{~g}, 2 \mathrm{mmol})$ and 4,4'-bipyridine ( $0.312 \mathrm{~g}, 2 \mathrm{mmol}$ ) in water ( $\sim 40 \mathrm{~mL}$ ) by heating the reaction mixture on a steam bath for $15-20 \mathrm{~min}$ to obtain a clear solution, followed by crystallization. The use of 1,2,4-triazole ( 1.104 g ) instead of $4,4^{\prime}$-bipyridine in the above reaction and microwaving (or heating) the reaction mixture to attain a final volume of $8-10 \mathrm{~mL}$ resulted in the formation of crystals of $\mathbf{2}$ in $70 \%$ yield.

The structures of $\mathbf{1}$ and $\mathbf{2}$ were determined using Bruker Smart Apex X-ray diffractometer. Intensity data were collected at room temperature (RT) using monochromated $\operatorname{Mo}(\mathrm{K} \alpha)(\lambda=0.7107 \AA)$ radiation. The structures were solved with SHELXS and subsequent refinements were performed with SHELXL ${ }^{36}$. All nonhydrogen atoms were refined anisotropically. H atoms attached to the aromatic ring of the 4-nba ligand and 4,4'-bipyridine were introduced in calculated positions and included in the refinement by riding on their respective parent C atoms. Technical details of data acquisition and selected crystal refinement results are given in Table 1.

## Results and Discussion

## Synthetic aspects, spectral and thermal characterization

The synthetic methodology for the preparation of $\mathbf{1}$ (or $\mathbf{2}$ ) is similar to the one employed by us earlier for the incorporation of N -donor ligands like N -methylimidazole or 2-methylimidazole ${ }^{34,35}$ in the

coordination sphere of Ca in $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(4-n b a)_{2}\right] 3$. A solution based synthesis was employed so as to obtain crystalline products suitable for structure determination. In this work, aqueous reactions of the N -heterocycles viz. 4,4'-bipyridine and 1,2,4-triazole were investigated with $\mathbf{3}$ under microwave irradiation or by heating on a water bath. Both methods afforded the same products as evidenced by the identical infrared, Raman and optical spectra (Supplementary Data, Fig. S1). However, the microwave-assisted synthesis resulted in product formation in good yield within a shorter reaction time. Use of stoichiometric 4,4'-bipyridine afforded $\mathbf{1}$ while an excess of 1,2,4triazole ( 8 moles per Ca ) was required to isolate $\mathbf{2}$. Compound 1 precipitated immediately from solution if less water was used, while for 2 excess of $1,2,4-$ triazole and minimum water was necessary in order to avoid the hydrolysis of the product to the tetraquacalcium compound 3 .

The composition of $\mathbf{1}$ (or $\mathbf{2}$ ) as consisting of Ca:water:4-nba:L ( $\mathrm{L}=\mathrm{N}$-heterocycle) in 1:2:2:1 ratio was inferred from elemental analytical data, the amount of 4-nbaH obtained by acidification of $\mathbf{1}$ (or 2) and the amount of $\mathrm{CaCO}_{3}$ residue obtained at $600^{\circ} \mathrm{C}$ by pyrolysis of $\mathbf{1}$ (or 2). A comparison of the infrared spectra of $\mathbf{1}$ ( or $\mathbf{2}$ ) with the IR spectrum of the precursor compound 3 revealed change of the profile of the IR spectra in the -OH region. Additionally, the spectra of the title compounds contain several more bands indicating the formation of new compounds. The Raman spectra of $\mathbf{1}$ ( o $\mathbf{2}$ ) exhibit an intense band at 1341 (or 1338) cm ${ }^{-1}$ which can be assigned for the symmetric stretching vibration of the nitro group. The DTA curve of 1 (Supplementary Data, Fig. S2) exhibits an endothermic event at $98^{\circ} \mathrm{C}$, which can be attributed for dehydration. This is further confirmed by heating 1 at $100{ }^{\circ} \mathrm{C}$ in an oven, wherein a mass loss, of $6.25 \%$, corresponding to the loss of two moles
of water is observed. The formation of an anhydrous compound is confirmed by the absence of the $\mathrm{O}-\mathrm{H}$ signal at $3600 \mathrm{~cm}^{-1}$ in the IR spectrum (Supplementary Data, Fig. S3), which reappears when the anhydrous compound is equilibrated over water showing successful rehydration. The exothermic peaks at 409 and $585{ }^{\circ} \mathrm{C}$ in DTA curve can be assigned for decomposition process leading to loss of organic moiety. The DTA curve of 2 (Supplementary Data, Fig. S2) exhibits an endothermic process at $117{ }^{\circ} \mathrm{C}$ which can be assigned for the loss of coordinated water, followed by continuous degradation with temperature as indicated by mass loss in TG curve. The second DTA (at $433{ }^{\circ} \mathrm{C}$ ) event is exothermic in nature and can be assigned for the decomposition of organic ligand. Compound 1 (or 2) exhibits diminished fluorescence as compared to that of free 4-nbaH (Supplementary Data, Fig. S4). Although the spectral and analytical studies revealed the presence of N -heterocycles in $\mathbf{1}$ (or $\mathbf{2}$ ) a crystal structure determination confirmed that 4,4'-bipyridine (or 1,2,4-triazole) are not bonded to the $\mathrm{Ca}(\mathrm{II})$ unlike in the case of N -methylimidazole or 2-methylimidazole ${ }^{34,35}$.

## Description of crystal structures

Both compounds crystallizing in centrosymmetric space groups are structurally related and exhibit several similarities. The compounds differ in terms of the N -heterocycle namely $4,4^{\prime}$-bipyridine in $\mathbf{1}$ and 1,2,4-triazole in 2, the location of two unique $\mathrm{Ca}(\mathrm{II})$ ions in 2 and the secondary interactions. The similarities include the eight coordination around the central $\mathrm{Ca}(\mathrm{II}), \mu_{2}$-tridentate binding mode of 4-nba ligand and edge sharing $\left\{\mathrm{CaO}_{8}\right\}$ polyhedral chain architecture, presence of a N -heterocycle in the lattice. The geometric parameters of the anionic 4nitrobenzoates (4-nba) and the N -heterocycles are in the normal range ${ }^{37}$ in both the compounds (Supplementary Data, Table S1 and S2).

Compound 1 crystallizes in the triclinic space group $P \overline{1}$ with all atoms located in general position. The asymmetric unit consists of (Supplementary Data, Fig. S5) an unique $\mathrm{Ca}(\mathrm{II})$, two crystallographically independent 4 -nitrobenzoate ligands, two terminal water molecules, and an unique 4,4-bipyridine molecule in the lattice. The central $\mathrm{Ca}(\mathrm{II})$ is eight coordinated and is bonded to two monodentate water molecules (O31, O32), and to six O atoms from four symmetry related 4-nba anions (Fig. 1), resulting in a distorted square antiprismatic $\left\{\mathrm{CaO}_{8}\right\}$ polyhedron
(Supplementary Data, Fig. S5). The surroundings of $\mathrm{Ca}(\mathrm{II})$ in $\mathbf{1}$ is similar to the one reported earlier for $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(4-\mathrm{nba})_{2}\right] \cdot 2 \mathrm{dmp} \quad(\mathrm{dmp}=3,5-$ dimethylpyrazole $)^{38}$. The $\mathrm{Ca}-\mathrm{O}$ bond distances (Table 2) vary between $2.3679(17)$ and $2.722(2) \AA$, while the $\mathrm{O}-\mathrm{Ca}-\mathrm{O}$ angles scatter in a very broad range from 50.04(5) to $155.45(7)^{\circ}$ indicating a distortion of the $\left\{\mathrm{CaO}_{8}\right\}$ coordination polyhedron. The Ca1-O31 and $\mathrm{Ca} 1-\mathrm{O} 32$ bonds are shorter at $2.372(2)$ and 2.388(2) $\AA$, respectively. However, these bonds of $\mathrm{Ca}(\mathrm{II})$ with the terminal aqua ligands are slightly longer as compared to the Ca-carboxylate bond distances $\mathrm{Ca} 1-\mathrm{O} 2$ and $\mathrm{Ca} 1-\mathrm{O} 12^{\mathrm{i}}\left(\mathrm{H}_{2} \mathrm{O}\right)$ at $2.3679(17)$ and 2.3698 (17), respectively. Both the unique 4-nba ligands function as $\mu_{2}-\eta^{2}: \eta^{1}$ bridging tridentate ligands (Fig. 1). The carboxylate oxygens O1 and O2 in the first unique 4 -nba ligand ( $\mathrm{O} 1, \mathrm{O} 2$ ) bind to $\mathrm{Ca}(\mathrm{II})$ at $\mathrm{Ca} 1-\mathrm{O} 1$ and $\mathrm{Ca} 1-\mathrm{O} 2$ distances of 2.4480 (19) and 2.7116 (19) $\AA$, respectively. The O 2 oxygen is further linked to a symmetry related $\mathrm{Ca}(\mathrm{II})^{\mathrm{ii}}$ at a distance of $2.3679(17) ~ \AA$ resulting in a $\mathrm{Ca} \cdots \mathrm{Ca}$ separation of $4.059(4) \AA$. The second unique ligand (O11,O12) also exhibits $\mu_{2}-\eta^{2}: \eta^{1}$ binding mode and binds to Ca1 in a similar fashion resulting in a different $\mathrm{Ca} \cdots \mathrm{Ca}$ separation of $4.049(4) \AA$ (Fig. 1).

To understand the crystal structure of 1, the binding of only one unique ligand with $\mathrm{Ca}(\mathrm{II})$ is first considered (Supplementary Data, Fig. S6). The binding of only one 4 -nba ligand ( $\mathrm{O} 1, \mathrm{O} 2$ ) results in the formation of discrete dimers with $\mathrm{Ca}^{\cdots} \mathrm{Ca}^{\mathrm{ii}}$ separations of $4.059(4) \AA$. Thus a pair of (O1, O2) ligands bonded to a pair of $\mathrm{Ca}(\mathrm{II})$ ions constitutes the basic building unit namely a tricyclic dicalcium-di(4nitrobenzoate) moiety. Each $\mathrm{Ca}(\mathrm{II})$ in the dimer is coordinated to a pair of terminal aqua ligands O31 and O32. Similarly, if we consider the $\mu_{2}-\eta^{2}: \eta^{1}$ binding mode of only the (O11, O12) ligand, a similar set of discrete dimers with $\mathrm{Ca} \cdots \mathrm{Ca}$ separations of 4.059(4) $\AA$ are formed and each $\mathrm{Ca}(\mathrm{II})$ is bonded to the terminal waters O31 and O32 (Supplementary Data, Fig. S6). The net result of the $\mu_{2}-\eta^{2}: \eta^{1}$ tridentate binding modes of the unique 4-nba ligands is linking of pairs of $\left\{\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}\right\}^{2+}$ units into an infinite chain extending along the direction of $a$ axis by alternating pairs of the crystallographically unique 4-nba ligands accompanied by alternating $\mathrm{Ca} \cdots \mathrm{Ca}$ separations of $4.059(4)$ and $4.049(4) \AA$, respectively (Fig. 2). A closer scrutiny reveals that the central $\left\{\mathrm{CaO}_{8}\right\}$ polyhedral chain exhibits an edge-sharing architecture, the shared edge being alternating pairs of

Fig. 1 - The crystal structure of $\mathbf{1}$ showing the atom labelling scheme and the eight coordination around $\mathrm{Ca}(\mathrm{II})$. Displacement ellipsoids are drawn at the $50 \%$ probability level excepting for the H atoms, which are shown as spheres of arbitrary radii. Intramolecular hydrogen bonding is shown by broken lines (top). The $\mu_{2}-\eta^{2}: \eta^{1}$ binding modes of the unique 4-nba ligands (bottom). Symmetry code: i) $-\mathrm{x}+1,-\mathrm{y}+1$, $-z+2$, ii) $-x,-y+1,-z+2$
$\mathrm{O} 2, \mathrm{O} 2^{\text {ii }}$ and $\mathrm{O} 12, \mathrm{O} 12^{\mathrm{i}}$ atoms, respectively (for symmetry code see Table 2). The unique 4-nitrobenzoates flank either side of the $\left\{\mathrm{CaO}_{8}\right\}$ polyhedral chain (Fig. 2).

All of the hydrogen atoms attached to the terminal waters O31 and O32 and the hydrogen atoms $\mathrm{H} 2, \mathrm{H} 3$, H5, H16, H24, H28 and H30 bonded to the carbon atoms of the unique 4 -nba or the $4,4^{\prime}$-bipyridine function as hydrogen donors while the oxygen atoms, $\mathrm{O}, \mathrm{O}, \mathrm{O} 4, \mathrm{O} 11, \mathrm{O} 13, \mathrm{O} 31$ and O32 and the nitrogen atoms N21 and N22 of 4,4'-bipyridine function as hydrogen acceptors resulting in three varieties of hydrogen bonding interactions (Table 3) viz $\mathrm{O}-\mathrm{H} \cdots \mathrm{N}$, $\mathrm{O}-\mathrm{H}^{\cdots} \mathrm{O}$ and $\mathrm{C}-\mathrm{H}^{\cdots} \mathrm{O}$, respectively. Out of the eleven hydrogen bonds listed in Table 3, two are intramolecular. It is interesting to note that the 4,4-bipyridine, which functions as a solvate links
adjacent one-dimensional chains with the aid of O$\mathrm{H}^{\cdots} \mathrm{N}$ interactions (Fig. 3).

Compound 2 crystallizes in the monoclinic space group C2/c. Its structure (Fig. 4) consists of two unique Ca (II) located on a two-fold axis, two crystallographically independent monodentate water molecules (O31 and O32), two unique 4-nba ligands and a crystallographically independent 1,2,4-triazole in the crystal lattice. As in $\mathbf{1}$ both the unique 4-nba ligands exhibit $\mu_{2}$-bridging tridentate binding mode (Supplementary Data, Fig. S7). The unique $\mathrm{Ca}(\mathrm{II})$ ions ( Ca 1 and Ca 2 ) are eight coordinated. The bonding situation around each unique Ca in $\mathbf{2}$ is very similar to that observed in 1. Hence, the unique ligands (O1, O2 and O11, O12), as well as the coordinated water molecules (O31, O32), are labeled as in compound 1. Due to the special position of the

Table 2 - Selected bond lengths and angles $\left(\AA \AA^{\circ}{ }^{\circ}\right.$ ) for $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(4-\mathrm{nba})_{2}\right] \cdot \mathrm{L}\left(4-\mathrm{nba}=4\right.$-nitrobenzoate; $\mathrm{L}=4,4$ ' $^{\prime}$ bipyridine $\mathbf{1} ; \mathrm{L}=1,2,4$-triazole $\left.\mathbf{2}\right)$

Fig. 2 - (top \& bottom) A view along ' $b$ ' showing a portion of an infinite chain extending along $a$-axis due to the $\mu_{2}-\eta^{2}: \eta^{1}$ tridentate binding modes of the unique ligands (O1, O2) and (O11, O12) with alternating $\mathrm{Ca} \cdots \mathrm{Ca}$ separations. Each $\mathrm{Ca}(\mathrm{II})$ in the chain is bonded to two monodentate water ligands O 31 and O 32 (top). The central chain of edge-sharing $\left\{\mathrm{CaO}_{8}\right\}$ polyhedra is flanked by the 4-nitrobenzoates. O2 and O12 are the oxygen atoms at the shared edges (bottom).
unique $\mathrm{Ca}(\mathrm{II})$ ions, Ca 1 is bonded to one unique ligand ( $\mathrm{O} 1, \mathrm{O} 2$ ) and one unique water (O31). Similarly, the second unique Ca 2 is bonded to ( O 11 , O12) and O32. The two terminal water molecules on Ca 1 (or Ca 2 ) can be accounted for by the symmetry generated aqua ligand O31 (or O32 ${ }^{\text {i }}$. Thus each $\mathrm{Ca}(\mathrm{II})$ is bonded to two oxygen atoms of monodentate water and six O atoms from four symmetry related 4 nba anions, resulting in a distorted square antiprismatic $\left\{\mathrm{CaO}_{8}\right\}$ polyhedron (Fig. S7) as in 1. Unlike in 1, the bond distances involving the terminal aqua ligands viz. Ca1-O31 (or the Ca2-O32) are the shortest at $2.3561(11) \AA(2.3584(11))$. The Ca1-O (Ca2-O) bond distances vary between $2.3561(11)$ and $2.7422(10) \AA(2.3584(11)$ and $2.5696(10)$ for Ca2),
while the $\mathrm{O}-\mathrm{Ca}-\mathrm{O}$ angles scatter in a very broad range from $49.64(3)$ to $155.85(4)^{\circ}(51.20(3)$ to $160.11(5)$ for Ca 2 ) indicating the distortion of the $\left\{\mathrm{CaO}_{8}\right\}$ coordination polyhedra. Both the unique 4-nba ligands behave as $\mu_{2}-\eta^{2}: \eta^{1}$ bridging tridentate ligands (Fig. S7) resulting in the formation of a tricyclic dicalcium-di(4-nitrobenzoate) building unit of the coordination polymer. The formation of a onedimensional polymeric structure can be explained on similar lines as for $\mathbf{1}$. Unlike in $\mathbf{1}$, two different chains (one for each unique Ca ) with both extending along the direction of $c$ axis are formed (Supplementary Data, Fig. S8). In view of the special position of Ca1 (or Ca 2 ), each chain exhibits a single $\mathrm{Ca} \cdots \mathrm{Ca}$ separation of $3.8569(4) \AA$ (or 4.0164 (4) $\AA$ in the case

Fig. 3 - The 4,4'-bipyridine solvate links adjacent chains with the aid of $\mathrm{O}-\mathrm{H}^{\cdots} \mathrm{N}$ interactions involving the coordinated waters (O31 and O32) and the N 21 and N 22 atoms of 4,4'-bipyridine in compound $\mathbf{1}$ (top). A view showing that 1,2,4-trizole serving as link between chains of Ca1 and Ca 2 in $\mathbf{2}$ with the aid of H -bonding interactions (bottom). For clarity only the oxygen atoms of the carboxylate coordinated to Ca (II) is shown

Fig. 4 - The crystal structure of $\mathbf{2}$ showing the atom labelling scheme and the eight coordination around the unique Ca (II). Displacement ellipsoids are drawn at the $50 \%$ probability level for the non-hydrogen atoms. Intramolecular H-bonding is shown in broken lines. Symmetry code: i) $-x+1, y,-z+1 / 2$, ii) $-x+1,-y+3,-z$, iii) $x,-y+3, z+1 / 2$, iv) $-x+1,-y+3,-z+1, v) x,-y+2, z-1 / 2$, vi) $-x+1,-y+2,-z+1$ (top). A view along ' $a$ ' showing a portion of an infinite chain extending along $c$-axis due to the $\mu_{2}-\eta^{2}: \eta$ tridentate binding mode of the first unique ligand (O1, O2) with Ca1 $\cdots \mathrm{Ca} 1$ separations of $3.8569(4) \AA$. (See Fig S8) Each Ca1 in the chain is bonded to two monodentate water ligands O 31 and $\mathrm{O} 31^{\mathrm{i}}$. The edge-sharing $\left\{\mathrm{CaO}_{8}\right\}$ polyhedral chain is flanked by the 4-nitrobenzoate wings (bottom).
of Ca 2 ). As in 1 the $\left\{\mathrm{CaO}_{8}\right\}$ polyhedral chain exhibits an edge-sharing architecture (Fig. 4, Supplementary Data, Fig S8) and is flanked by 4-nitrobenzoate wings.

Compound 2 exhibits four varieties of hydrogen bonding interactions (Table 3) viz. O-H $\cdots \mathrm{N}, \mathrm{O}-$ $\mathrm{H} \cdots \mathrm{O}, \mathrm{N}-\mathrm{H} \cdots \mathrm{O}$ and $\mathrm{C}-\mathrm{H}^{\cdots} \mathrm{O}$, respectively. All of the hydrogen atoms attached to the terminal waters O31 and O32, the H21N and H22 attached to N21 and C22 of 1,2,4-triazole and the hydrogen atoms $\mathrm{H} 2, \mathrm{H} 5$ and H 16 of the unique 4-nba function as hydrogen donors while the oxygen atoms, $\mathrm{O} 1, \mathrm{O} 3, \mathrm{O} 11, \mathrm{O} 13$ and O 31 and the nitrogen atoms N 22 and N 23 of 1,2,4-triazole function as hydrogen acceptors resulting in a total of
nine hydrogen bonds. The 1,2,4-triazole molecule functions as a solvate and is not bonded to $\mathrm{Ca}(\mathrm{II})$. Instead the N -hetrocycle links the one-dimensional chain of Ca 1 with the chain of Ca 2 via $\mathrm{O} 31-$ H31A $\cdots \mathrm{N} 23$, O32-H32B $\cdots \mathrm{N} 22$, C22-H22-O1 and $\mathrm{N} 21-\mathrm{H} 21 \mathrm{~N} \cdots \mathrm{O} 11$ hydrogen bonding interactions (Fig. 3). As a result the structure is organized in the following sequence viz. chain $1(\mathrm{Ca} 1) \cdots 1,2,4-$ triazole $\cdots$ chain 2 (Ca2) $\cdots 1,2$, 4-triazole and so on.

In addition to compounds $\mathbf{1}$ and $\mathbf{2}$ described in this work, ten more structures of $\mathrm{Ca}(\mathrm{II})$ compounds based on 4-nitrobenzoic acid are archived in the Cambridge Structural Database (CSD) ${ }^{37}$. The rich and variable structural chemistry of calcium can be evidenced from

Table 4 - Comparative structural features of 4-nitrobenzoates (4-nba) of Ca (II)

Abbreviations used: S.G. = space group; C.N. $=$ Coordination number ${ }^{\text {a }}$ Number in parentheses is the number of 4-nba linked to each unique Ca ; C.S = Coordination sphere; $\mathrm{D}=$ Dimensionality; ${ }^{\mathrm{b}}$ unique 4-nba ligand; ${ }^{\mathrm{c}}$ two unique $\mathrm{Ca}(\mathrm{II}) ;{ }^{\mathrm{d}}$ molecular solid;
${ }^{e}$ chain of $\left\{\mathrm{CaO}_{6}\right\}$ octahedra bridged by two carboxylate C ; ${ }^{\mathrm{f}} \mathrm{chain}$ of $\left\{\mathrm{CaO}_{4} \mathrm{~N}_{2}\right\}$ octahedra bridged by two carboxylate C ; ${ }^{\mathrm{g}}$ chain of edge sharing $\left\{\mathrm{CaO}_{5} \mathrm{~N}\right\}$ bioctahedra bridged by four carboxylate carbons; ${ }^{\text {h }}$ edge-sharing $\left\{\mathrm{CaO}_{6} \mathrm{~N}\right\}$ polyhedra with a carboxylate C bridge; NMF = N-methyl-formamide; $\mathrm{BA}=$ benzamide; pyr $=$ pyrazole; $\mathrm{L}^{1}=\mathrm{N}$-methylimidazole; $\mathrm{L}^{2}=2$-methylimidazole; dmp $=3,5-$ dimethylpyrazole; 2 -ap = 2-aminopyridine; $\operatorname{Im}=$ imidazole
the structurally characterized 4-nitrobenzoate compounds of Ca (II) listed in Table $4^{25,30,34,35,38-42}$. In all these compounds (except entry No. 10) which crystallize in centrosymmetric space groups, the coordination number of the central metal varies from six (entry nos. 1-4 and 12) to eight showing the structural flexibility of $\mathrm{Ca}(\mathrm{II})$. Although this list has four examples of $\mathrm{Ca}(\mathrm{II})$ bonded to N -donor ligands, the oxophilic nature of Ca can still be evidenced by the fact that a maximum of two N -donor ligands (entry no. 3) can be incorporated into the calcium coordination sphere. Excepting the last four entries in Table 4 which are molecular solids, the rest are onedimensional (1D) coordination polymers and contain one or two or no coordinated water molecules. In seven of the eight coordination polymers each $\mathrm{Ca}(\mathrm{II})$ is bonded to four carboxylate groups as originally predicted by Einspaar and Bugg ${ }^{43}$ for calcium carboxylates. In the molecular solids each $\mathrm{Ca}(\mathrm{II})$ is bonded to either one ${ }^{30,41}$ or two ${ }^{25,42}$ 4-nitrobenzoates. In addition to being a charge balancing anion in all the compounds, the 4-nitrobenzoate moiety functions as a monodentate $\left(\eta^{1}\right)$ or bidentate $\left(\eta^{2}\right)$ or a bridging ligand. In all the 1-D coordination polymers, the 4-nba ligand exhibits a bridging binding mode which is responsible for the extended structure. Although both $\mu_{2^{-}}$and $\mu_{3}$-bridging binding modes are observed
the symmetric $\mu_{2}-\eta^{1}: \eta^{1}$ binding mode is observed in five compounds and the $\mu_{2}-\eta^{2}: \eta^{1}$ tridentate binding mode is observed in four different compounds including 1 and 2. In addition, $\mu_{2}-\eta^{2}$ bridging where only one carboxylate oxygen binds to two different $\mathrm{Ca}(\mathrm{II})$ (entry no. 5) and a $\mu_{3}-\eta^{2}: \eta^{1}$ bridging tridentate binding mode are also observed. Only three coordination polymers in Table 4 have a maximum of two moles of water, while four are anhydrous. The degree of hydration of a $\mathrm{Ca}(\mathrm{II})$-carboxylate is an important property which determines its structure. In the case of 4-nitrobenzoic acid linker, the degree of hydration can explain the dimensionality of the Ca (II) compound as $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{4}(4-\mathrm{nba})_{2}\right] 3$ containing four coordinated water molecules is a molecular solid (zero dimensional) while the partial removal of the water molecules as in $\mathbf{1}$ (or 2) leads to a chain structure. The coordination ploymers listed in Table 4 exhibit different kinds of polyhedral linking. For example, the chain of $\left\{\mathrm{CaO}_{6}\right\}$ octahedra (entry nos 1 and 2) are bridged by a pair of carboxylate carbon atoms (Supplementary Data, Fig. S9). A similar bridging by carboxylate C is observed for the anhydrous coordination polymer $\left[\mathrm{Ca}(\mathrm{pyr})_{2}(4-\mathrm{nba})_{2}\right]$ (pyr=pyrazole) but the octahedra in this case are made up of $\left\{\mathrm{CaN}_{2} \mathrm{O}_{4}\right\}$ (Supplementary Data, Fig. S9). In the ladder coordination polymer $\left[\mathrm{Ca}\left(\mathrm{L}^{1}\right)(4-n b a)_{2}\right]$

Fig. 5 - A chain of edge-sharing bioctahedra bridged by four carboxylate carbon atoms in $\left[\mathrm{Ca}\left(\mathrm{L}^{1}\right)(4-\mathrm{nba})_{2}\right]\left(\mathrm{L}^{1}=\mathrm{N}\right.$-methyl-imidazole $)$. For clarity only the N atom of $\mathrm{L}^{1}$, oxygen atoms of the carboxylate and the bridging carbons are shown. (Fig S12 shows all the ligand atoms)
$\left(\mathrm{L}^{1}=\mathrm{N}\right.$-methylimidazole) $\left\{\mathrm{CaNO}_{5}\right\}$ edge-sharing bioctahedra bridged by four carboxylate carbons are linked into an infinite chain (Fig. 5, Supplementary Data, Fig. S10). In the case of the seven coordinated mixed ligand $\mathrm{Ca}(\mathrm{II})$ compound $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)\left(\mathrm{L}^{2}\right)(4-\mathrm{nba})_{2}\right]$ $\mathrm{L}^{2}=2$-methylimidazole, the $\left\{\mathrm{CaO}_{6} \mathrm{~N}\right\}$ polyhedra exhibit an edge sharing architecture like the title compounds. Interestingly the adjacent polyhedra in the chain are bridged by a carboxylate carbon resulting in an infinite chain (Fig. S10). A study of this series of compounds reveals that the presence of each of a symmetric bridging ( $\mu_{2}-\eta^{1}: \eta^{1}$ ) ligand results in the polyhedra being bridged by a carboxylate carbon. The eight coordinated title compounds 1 and 2 and $\left[\mathrm{Ca}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}(4-\mathrm{nba})_{2}\right] \cdot 2 \mathrm{dmp}$ exhibit an edge sharing architecture of the $\left\{\mathrm{CaO}_{8}\right\}$ polyhedra.

## Conclusions

The synthesis, spectra and structures of two new calcium coordination polymers based on a chain of edge sharing $\left\{\mathrm{CaO}_{8}\right\}$ polyhedra are reported. A comparative study of eight $\mathrm{Ca}(\mathrm{II})$ coordination polymers based on the 4-nitrobenzoate linker reveals a rich and variable structural chemistry. The two calcium coordination polymers described herein are two new additions to a growing list of structurally characterized alkaline-earth metal coordination polymers based on 4-nitrobenozic acid linker.

## Supplementary Data

Deposition Numbers CCDC 892774 and CCDC 892773 contain the supplementary crystallographic data for the structures of (1) and (2) described in this
paper. These data are provided free of charge by the joint Cambridge Crystallographic Data Centre and Fachinformationszentrum Karlsruhe Access Structures service www.ccdc.cam.ac.uk/structures. Supplementary Data associated with this article are available in the electronic form at http://nopr.niscair.res.in/jinfo/ijca/IJCA_60A(06)785796_SupplData.pdf.

## Acknowledgement

The authors thank Dr. K Ravikumar, CSIR-Indian Institute of Chemical Technology Hyderabad, India for the single crystal data of $\mathbf{2}$ reported in this paper. Financial assistance to the School of Chemical Sciences (formerly Department of Chemistry), Goa University, under the Special Assistance Program (DSA-1) of UGC-India, is gratefully acknowledged.
